

The Archipelago Climate Initiative Year One – 2025/2026 Results

by

Queen Arun Sandhya

October 2nd 2026

Executive Summary

The four top emitters of CO₂ in the world, are US, India, Russia, and China.

In 2024, there was very little hope of reducing the CO₂ emissions in the world.

Lots of countries had agreed to the Paris Agreement but were very far from managing their CO₂ emissions adequately to keep the global temperature rise between 1.5°C-2.0°C.

There was also an energy security issue for many countries, as they had to purchase oil, and supply was expensive and there was a concern, supplies of oil could run out altogether.

The Archipelago Climate Initiative was started in Oct 2025, to reduce these four countries' CO₂ emissions.

This initiative has seen significant progress in the top four CO₂ emitting countries in reducing CO₂ emissions helping to slow down global temperature rise.

To date, China and Russia have seen a 40% drop in CO₂ emissions, with renewables being used instead.

Both the risks to energy security, and the global temperature rise, are being mitigated by The Archipelago Climate Initiative.

Introduction

In October 2024 the Archipelago was designed and devised by Aruna Sandhya Koya.

The Archipelago included Counsel, Archipelago Community Ltd, and The Archipelago Fund

In March 2025 Aruna Sandhya Koya, CEO, registered Archipelago Community Ltd in the United Kingdom.

Archipelago Counsel, a meeting point for World Leaders, was established.

At an Archipelago Counsel meeting in October 2025, with multiple oil customer countries, it was decided that there was an oil supply issue and this would result in an energy security issue.

The Archipelago Climate initiative's goal:

Reduce CO₂ emissions in the four highest CO₂ emitting countries, to slow down global temperature rise

The Archipelago Climate Initiative Progress.

Aruna Sandhya Koya's Archipelago Community Ltd is a new supplier of Crude and Brent oil to many countries.

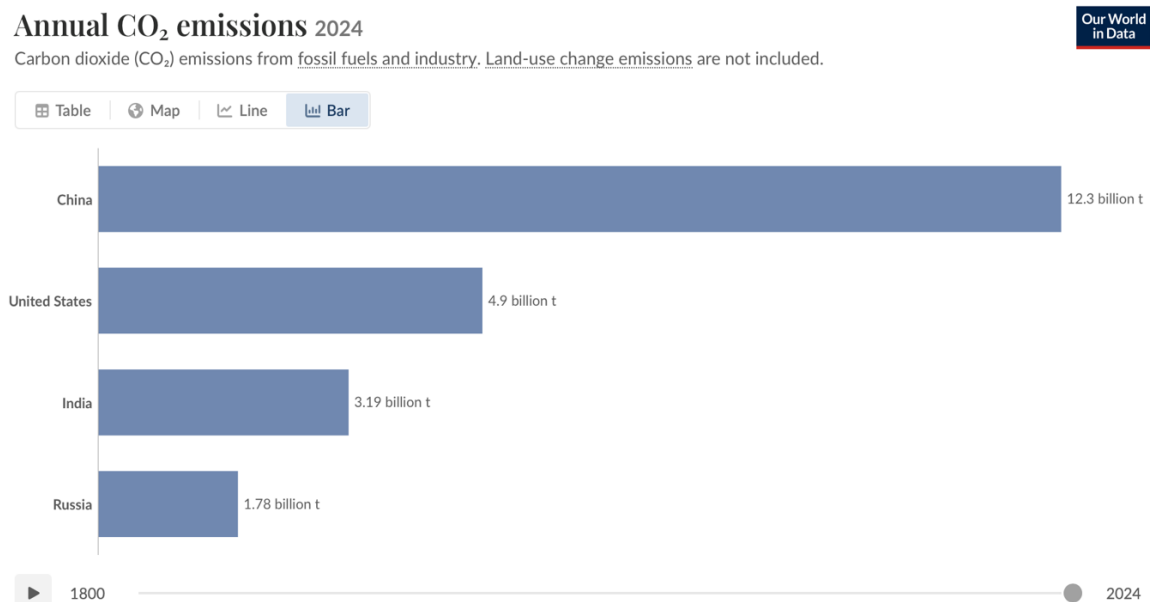

The initiative included incentives from Archipelago Community Ltd, for all oil purchasing countries to reduce their consumption of oil.

Supply was managed to provide energy security and increase uptake of renewables across the world.

By providing a supply to meet the four country's needs, whilst also reducing consumption over a period of three years, to guarantee energy security, there was a strategic effort to reduce the CO₂ emissions.

The top four CO₂ emitting countries are China, India, Russia and the US.

Here are their CO₂ emissions in tons as of 2024.

Aruna Sandhya Koya, implemented a strategy for all four countries, where the consumption of oil would be ramped down, and replaced with renewables between 2025-2028.

The countries were incentivized to take part.

The pricing of the oil was staged over three years.

The first three years, between 2025-2028, they were given one bulk price that would be maintained over three years. This was against all previous market patterns.

Once the requirement for bulk oil purchases, had reduced as they used more renewables, they would go to a different pricing plan, where they would only buy a small amount of oil, just in time, thereby reducing their energy costs dramatically.

Energy Security Policy

To facilitate the just in time demand for oil, there seven oil reservoirs set up globally, so oil supply was never very far or out of reach for any country in the world.

This provided all the countries energy security over the next five years for oil, so they were guaranteed an energy supply and as demand for oil decreased, and the renewables uptake would see them become self-sufficient in terms of energy requirements.

The ramp down from Oil and Gas

This ramp down from use of oil and gas, would mean that CO₂ emissions would be reduced. The aim is for some countries to CO₂ emissions altogether.

In the four target countries that were the highest emitters of CO₂, the Archipelago Climate Initiative went further.

Aruna Sandhya Koya led the conversations with the Governments of each country, to recommend alternative energy supplies to the oil / fossil fuels, for the companies. Energy research was carried out, and it was agreed that the four target countries would share the Intellectual Property Rights, where any new developments occurred.

Progress Year 1 (2025-2026)

China – 2025 - this involved managing consumption and switching to renewables at an accelerated rate of adoption. They have seen significant progress.

United States – 2025 - yet to commence with oil and gas. The US has seen an increase in adoption of electric cars however in the past two years. They have committed to managing energy consumption, making grid efficiency savings, and building solar farms, specifically to meet the demand for datacenters.

Russia – In 2025 this involved using and building up their hydro-electric estate as well as using solar farms. They have seen significant progress.

India – yet to commence. They have been adopting solar, steadily to reduce demands for oil and gas. As well as, adopting hydro-electric and solar farms.

Results of the Archipelago Climate Initiative – Year 1. (Oct 2025 – Oct 2026)

	2024/2025 CO ₂ tonnes per year	2025/2026	2026/2027	Target for October 2027 CO ₂ in tonnes per year
US	4.9	0%		Below 100mn tonne
India	3.19	-25%		Below 100mn tonne
China	12.3	-40%		Below 100mn tonne
Russia	1.73	-40%		Below 100mn tonne

Significant progress can be evidenced, of a reduction in CO₂ emissions in two out of four

countries.

The level of reduction in emissions, attained by China and Russia, set an example for all other countries, as well as the key four countries taking part.

This level of reduction must be sustained, for the next three years, for a slowdown of global temperature rise.

This shift in energy policy is also resulting in a reduction in air pollution levels.

Other countries are joining the reduction in oil and gas consumption, and commitments have been made. There are continued pressures, from technology availability and adoption timelines, as well as costs.

Summary

Oil and gas usage was resulting in CO₂ emissions impacting the global temperature of the planet. The Archipelago Climate Initiative was devised, to reduce CO₂ emissions in the four highest emitting countries. It is making progress with this target. Two of the four target countries have reduced emissions, but there is more to be done to have significant impact.
